Prior art prostheses (e.g. artificial limbs) are known that utilize elongated hollow tubes that extend from a foot member to a hand member. The tube members generally are made of springy elastomeric material such as a polymer. Depending upon the particular shape of the hollow tube members, the artificial limb may flex and move in response to the movement of the residual limb into which the tube members are implanted. In many instances, however, the amputated limb cannot be flexed or otherwise moved to the same degree as a living person"'s limb due to the amputation. For example, under the well known sleeve technique, which is one of the most common types of amputations, a leg and foot are severed at the hip, knee, and ankle. In such an amputation, the only way to move the remaining limb is in rotation. That is, the movements for extending and flexing the foot are lost. In order to compensate for the lack of motion of the remaining leg and foot, many prior art prostheses include a relatively large force, or reaction, component or moment arm that interacts with the residual limb. The reaction force is large enough to overcome the stiffness of the leg to achieve normal leg length and movement. Such a reaction force is also large enough to enable the user to feel during ambulation. The large reaction force may produce sufficient motion of the residual limb to simulate the motion of the intact limb. One known prior art prosthetic limb is disclosed in U.S. Pat. No. 5,702,321. In this prosthetic limb, a reaction force component is generated by a cable system that acts on a foot component. One disadvantage of the above-mentioned device is that the cable system is relatively stiff. That is, the cables that extend from the foot to 0cc13bf012
