We analyze the concept of metamaterials as microscopic components that are distinct from the materials they contain. Metamaterials are systems in which the constituent materials have been transformed at a length scale larger than what is relevant to their mechanical and optical properties. In addition to classical materials, micro- and nanostructured metamaterials can contain particle-like, waveguide-like, or resonator-like components that interact and can be assembled to mimic the properties of their macroscopic counterparts in an almost infinite range of frequency, mechanical, thermal, dielectric, and electromagnetic properties. Metallic and ceramic resonators and waveguides are two example structures. We describe metamaterials as collections of constituent elements. These elements must be in one-to-one correspondence with (1) the modes of specific wave types, (2) the interactions between the wave modes, and (3) the properties of the elements. Here, we consider the interactions between metamaterials, analytically predict the implications of what we call the effective permittivity, and examine two microchip cases as examples.The No. 1 Ladies Professional Golf Association event in the United States and No. 2 in the world, the year-end Championships, returns to Muirfield Village Golf Club Monday through Wednesday.
