the current version of the drivers includes fixes for windows 8/7, and an embedded.pdf printer that works with xp, vista and 7. with a first glance, though, there is one huge blemish: you need a usb port to use it. if you do not know, then allow me to explain what a pdf is. it is basically a microsoft portable document format file (.pdf) file is an electronic file format that describes the appearance of a printed page. it is an electronic file which can be read in most commercial software packages that offer pdf printing. the manual use the same usb port which you're using for your usb hub for connecting another usb device like a mouse or keyboard, this is a good idea, the output from the usb hub will help the other devices use power more efficiently. the pinout diagram shows a chip on the right that represents the a/d i/o pins. the msb/lsb pairs are line '0' through line '5', and line '6' through line '11'. the lsb is the lowest order bit of the a/d channel and the msb is the highest order bit. the main three bit signal is channel '0'. the a/d resolution is the number of bits used for signal resolution. for example, a 16-bit a/d converter requires a 16-bit input, and hence the minimum input is defined as 0 and maximum as 65535. thus, to read a 10-bit a/d converter, you'd have to range from '0' to '1023'. in practice, the device will discard the value once it crosses the input range. the usb bus uses a differential data transfer of '+5 volts and -5 volts (also referred to as signaling 1 and signaling 2). using this data transfer, the maximum bus data rate for the usb bus is up to 12 megabytes per second, but the typical data transfer rate for the usb bus is 5 megabytes per second (which is 50 percent of the maximum).

first the power supply cord is attached to the front of the b-control, then the remote control is attached to the right side of the control deck. the remote control has the following controls: record, pause, ff crossfade, a pointer icon, record button, pause button, and a switch to change the white lights on the controller from red to green, blue, purple, pink, orange, and white. how do i get the best sound from my behringer audio console? get the right driver! making sure that your audio card is selected for the output device allows you to listen to your behringer dj console through your computer's speakers. for best results, you should select the high-quality asio driver or the wasapi driver. both drivers use the same configuration options (such as the sample rate, the number of channels, etc). if you are still having problems with sound quality, try playing the audio files in windows' own sound player rather than from the computer's default program. the bcd2000 is a professional dj system that allows you to easily mix music from your cds or digital media, then instantly play a perfect loop of the master output mix. this allows the professional dj to easily set up a new song without needing to load up samples, wav files, etc. alternatively, you can run: msinfo32. once the installation is done, and the usb stick is working correctly, you have one more option to use the mixer: either press the "+" (+) button, or double-click the usb stick's icon under "device manager", and select "add a device". if the yellow warning sign doesn't reveal the issue, it does tell you that device manager has generated an error code, which you can verify to determine the reason. usually, it comes down to a hardware conflict of some sort, or missing or not correctly installed the driver.
