myLittleAdmin for SQL Server is a client/server application allowing you to manage all objects of your SQL Server 2000/2005 databases through a web browser. "If you think about it, though, a user that is using SQL Server Management Studio to work with an SQL Server instance is almost always connected to the instance via a network-based connection. That network connection has to go through a network device that is designed to filter and verify the connections. The device is designed to determine if the connection is authorized and if not, to drop the connection." "A network-based connection is a much slower connection than a network adapter connection, and this is why authentication is important to your application. The older connection types did not have this authentication requirement. They were much faster than network-based connections, so they were used without authentication. When that connection is made on the server side, the authentication information is used to verify that the user is properly authorized and connected. This authentication information is stored in SQL Server in the logon and sysadmin fixed-length string. " "The sysadmin connection type is the fastest connection type available, but it requires a fixed-length connection string. The logon connection type requires a username and password, which are validated when the connection is made, so there are no connection delays." "The network adapter connection requires an authentication string of an exact length. The length of the string is determined by the current size of the net_logon variable in the registry. These connection strings are validated before the connection is made, and only connections with the right authentication string are allowed to continue. Network adapter connections are relatively slow, so authentication is also important to your application. In addition, the net_logon registry entry is a fixed-length value that is stored in the registry. If the registry size is not increased, the connections will not be allowed to continue." "When a network adapter connection is made, the authentication string is validated, and if it is incorrect, the connection is dropped. This connection type is useful for remote network connections and for connecting to servers on a local network when the SQL Server service is running on a different computer on the local network. " "The named pipe connection requires a connection string of exactly 3 characters. Because the connection string is in the form of a pipe, named pipe connections are fast. Because these connections are specific to a process that owns the pipes, a named pipe connection can be reused, but only between the processes
